Decision Theory: High Level View

# What types of problems are we solving?

- In data science problems, we generally need to:
  - Make a decision
  - Take an action
  - Produce some output
- Have some evaluation criterion

### **Actions**

#### Definition

An action is the generic term for what is produced by our system.

### **Examples of Actions**

- Produce a 0/1 classification [classical ML]
- ullet Reject hypothesis that  $\theta=0$  [classical Statistics]
- Written English text [image captioning, speech recognition, machine translation ]
- What's an action for predicting where a storm will be in 3 hours?
- What's an action for a self-driving car?

(NYU CDS)

### **Evaluation Criterion**

Decision theory is about finding "optimal" actions, under various definitions of optimality.

### Examples of Evaluation Criteria

- Is classification correct?
- Does text transcription exactly match the spoken words?
  - Should we give partial credit? How?

(NYU CDS)

- How far is the storm from the prediction location? [for point prediction]
- How likely is the storm's location under the prediction? [for density prediction]

## Real Life: Formalizing a Business Problem

- First two steps to formalizing a problem:
  - ① Define the action space (i.e. the set of possible actions)
  - 2 Specify the evaluation criterion.
- Formalization may evolve gradually, as you understand the problem better

### Inputs

Most problems have an extra piece, going by various names:

- Inputs [ML]
- Covariates [Statistics]

### Examples of Inputs

- A picture
- A storm's historical location and other weather data

(NYU CDS)

A search query

"Outcomes" or "Output" or "Label"

Inputs often paired with outputs or outcomes or labels

Examples of outcomes/outputs/labels

- Whether or not the picture actually contains an animal
- The storm's location one hour after query
- Which, if any, of suggested the URLs were selected

(NYU CDS)

### Typical Sequence of Events

Many problem domains can be formalized as follows:

- Observe input x.
- 2 Take action a.
- Observe outcome y.
- **©** Evaluate action in relation to the outcome (via a loss function  $\ell(a, y)$ )

#### Note

- Outcome y is often independent of action a
- But this is not always the case:
  - search result ranking
  - automated driving

### Formalization: The Spaces

### The Three Spaces:

- ullet Input space:  ${\mathfrak X}$
- ullet Action space:  ${\cal A}$
- Outcome space: y

### Concept check:

- What are the spaces for linear regression?
- What are the spaces for logistic regression?
- What are the spaces for a support vector machine?

### Some Formalization

### The Spaces

ullet  $\chi$ : input space

• y: outcome space

ullet  ${\cal A}$ : action space

### Prediction Function (or "decision function")

A **prediction function** (or **decision function**) gets input  $x \in \mathcal{X}$  and produces an action  $a \in \mathcal{A}$ :

$$\begin{array}{cccc} f: & \mathcal{X} & \to & \mathcal{A} \\ & x & \mapsto & f(x) \end{array}$$

### Loss Function

A loss function evaluates an action in the context of the outcome y.

$$\ell: \mathcal{A} \times \mathcal{Y} \to \mathbf{R}$$
 $(a,y) \mapsto \ell(a,y)$ 

# **Evaluating a Prediction Function**

- ullet Loss function  $\ell$  evaluates a single action
- How to evaluate the prediction function as a whole?
- We will use the standard statistical learning theory framework.

# Statistical Learning Theory

## A Simplifying Assumption

- Assume action has no effect on the output
  - includes all traditional prediction problems
  - what about stock market prediction?
  - what about stock market investing?
- What about fancier problems where this does not hold?
  - often can be reformulated or "reduced" to problems where it does hold
  - see literature on reinforcement learning

# Setup for Statistical Learning Theory

- Assume there is a data generating distribution  $P_{X \times Y}$ .
- All input/output pairs (x, y) are generated i.i.d. from  $P_{X \times Y}$ .
- Want prediction function f(x) that generally "does well on average":

 $\ell(f(x), y)$  is usually small, in some sense

• How can we formalize this?

### The Risk Functional

#### Definition

The **risk** of a prediction function  $f: \mathcal{X} \to \mathcal{A}$  is

$$R(f) = \mathbb{E}\ell(f(x), y).$$

In words, it's the **expected loss** of f on a new exampe (x,y) drawn randomly from  $P_{\mathfrak{X}\times\mathfrak{Y}}$ .

### Risk function cannot be computed

Since we don't know  $P_{X \times Y}$ , we cannot compute the expectation.

(NYU CDS)

But we can estimate it...

## The Bayes Prediction Function

#### Definition

A Bayes prediction function  $f^*: \mathcal{X} \to \mathcal{A}$  is a function that achieves the *minimal risk* among all possible functions:

$$f^* \in \operatorname*{arg\,min}_f R(f),$$

where the minimum is taken over all functions from X to A.

- The risk of a Bayes prediction function is called the Bayes risk.
- A Bayes prediction function is often called the "target function", since it's the best prediction function we can possibly produce.

## Example: Least Squares Regression

- Spaces: A = y = R
- Square loss:

$$\ell(a,y) = (a-y)^2$$

Risk:

$$\begin{array}{rcl} R(f) & = & \mathbb{E}\big[(f(x)-y)^2\big] \\ (\text{homework} \implies) & = & \mathbb{E}\big[(f(x)-\mathbb{E}[y|x])^2\big] + \mathbb{E}\big[(y-\mathbb{E}[y|x])^2\big] \end{array}$$

• So Bayes prediction function is

$$f^*(x) = \mathbb{E}[y|x]$$

# Example 2: Multiclass Classification

- Spaces:  $A = \mathcal{Y} = \{1, \dots, k\}$
- 0-1 loss:

$$\ell(a,y) = 1 (a \neq y) := \begin{cases} 1 & \text{if } a \neq y \\ 0 & \text{otherwise.} \end{cases}$$

Risk:

$$R(f) = \mathbb{E}[1(f(x) \neq y)] = 0 \cdot \mathbb{P}(f(x) = y) + 1 \cdot \mathbb{P}(f(x) \neq y)$$
$$= \mathbb{P}(f(x) \neq y),$$

which is just the misclassification error rate.

• Bayes prediction function is just the assignment to the most likely class:

$$f^*(x) \in \underset{1 \leqslant c \leqslant k}{\operatorname{arg\,max}} \mathbb{P}(y = c \mid x)$$

# But we can't compute the risk!

- Can't compute  $R(f) = \mathbb{E}\ell(f(x), y)$  because we **don't know**  $P_{X \times Y}$ .
- One thing we can do in ML/statistics/data science is

assume we have sample data.

Let 
$$\mathcal{D}_n = ((x_1, y_1), \dots, (x_n, y_n))$$
 be drawn i.i.d. from  $\mathcal{P}_{\mathcal{X} \times \mathcal{Y}}$ .

• Let's draw some inspiration from the Strong Law of Large Numbers: If  $z, z_1, ..., z_n$  are i.i.d. with expected value  $\mathbb{E}z$ , then

$$\lim_{n\to\infty}\frac{1}{n}\sum_{i=1}^n z_i=\mathbb{E}z,$$

with probability 1.

## The Empirical Risk

Let 
$$\mathcal{D}_n = ((x_1, y_1), \dots, (x_n, y_n))$$
 be drawn i.i.d. from  $\mathcal{P}_{\mathfrak{X} \times \mathfrak{Y}}$ .

#### Definition

The **empirical risk** of  $f: \mathcal{X} \to \mathcal{A}$  with respect to  $\mathcal{D}_n$  is

$$\hat{R}_n(f) = \frac{1}{n} \sum_{i=1}^n \ell(f(x_i), y_i).$$

• By the Strong Law of Large Numbers,

$$\lim_{n\to\infty} \hat{R}_n(f) = R(f),$$

almost surely.

• But we want to find the f that **minimizes** R(f) - will minimizing  $\hat{R}_n(f)$  be good enough?

We want risk minimizer, is empirical risk minimizer close enough?

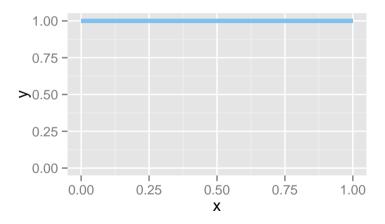

#### Definition

A function  $\hat{f}$  is an empirical risk minimizer if

$$\hat{f} \in \operatorname*{arg\,min}_{f} \hat{R}_{n}(f),$$

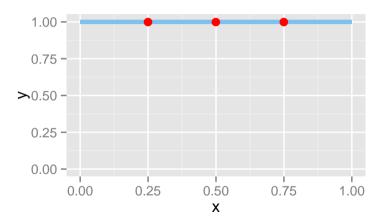

where the minimum is taken over all functions.

 $P_{\mathfrak{X}} = \mathsf{Uniform}[0,1], \ Y \equiv 1 \ (\mathsf{i.e.} \ Y \ \mathsf{is always} \ 1).$ 

 $\mathcal{P}_{\chi \times y}$ .

 $P_{\mathfrak{X}} = \mathsf{Uniform}[0,1], \ Y \equiv 1 \ (\mathsf{i.e.} \ Y \ \mathsf{is always} \ 1).$ 

A sample of size 3 from  $\mathcal{P}_{X \times Y}$ .

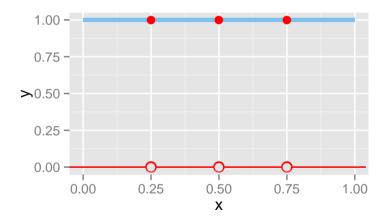

$$P_{\mathcal{X}} = \mathsf{Uniform}[0,1], \ Y \equiv 1 \ (\mathsf{i.e.} \ Y \ \mathsf{is always} \ 1).$$

A proposed prediction function:

$$\hat{f}(x) = 1(x \in \{0.25, 0.5, 0.75\}) = \begin{cases} 1 & \text{if } x \in \{0.25, .5, .75\} \\ 0 & \text{otherwise} \end{cases}$$

$$P_{\mathfrak{X}} = \mathsf{Uniform}[0,1], \ Y \equiv 1 \ (\mathsf{i.e.} \ Y \ \mathsf{is always} \ 1).$$

Under square loss or 0/1 loss:  $\hat{f}$  has Empirical Risk = 0 and Risk = 1.

26 / 29

- ERM led to a function f that just memorized the data.
- How to spread information or "generalize" from training inputs to new inputs?
- Need to smooth things out somehow...
  - A lot of modeling is about spreading and extrapolating information from one part of the input space  $\mathcal X$  into unobserved parts of the space.
- One approach: "Constrained ERM"
  - Instead of minimizing empirical risk over all prediction functions,
  - constrain to a particular subset, called a hypothesis space.

# Hypothesis Spaces

#### Definition

A hypothesis space  $\mathcal{F}$  is a set of functions mapping  $\mathcal{X} \to \mathcal{A}$ .

• It is the collection of prediction functions we are choosing from.

### Want Hypothesis Space that...

- Includes only those functions that have desired "regularity"
  - e.g. smoothness, simplicity

(NYU CDS)

Easy to work with

Example hypothesis spaces?

# Constrained Empirical Risk Minimization

- ullet Hypothesis space  $\mathcal{F}$ , a set of [prediction] functions mapping  $\mathcal{X} \to \mathcal{A}$
- ullet Empirical risk minimizer (ERM) in  ${\mathcal F}$  is

$$\hat{f}_n \in \operatorname*{arg\,min}_{f \in \mathcal{F}} \frac{1}{n} \sum_{i=1}^n \ell(f(x_i), y_i).$$

ullet Risk minimizer in  $\mathcal F$  is  $f_{\mathcal F}^*\in \mathcal F$  , where

$$f_{\mathcal{F}}^* \in \underset{f \in \mathcal{F}}{\operatorname{arg\,min}} \mathbb{E}\ell(f(x), y).$$
